

## LECTURE 25

### LINE INPUT / OUTPUT (K&R, § 7.7)

input	<code>fgets</code>
	<code>char *fgets(char *line, int maxline, FILE *fp)</code>
	<code>fgets</code> is like <code>getline()</code> from a file
	reads the next input line (including '\n') from file <code>fp</code> into the char array <code>line</code>
	at most, <code>maxline - 1</code> chars will be read
output	a terminal '\0' is added at the end
	returns a pointer to <code>line</code>
	(or NULL if it reaches EOF)
	<code>fputs</code>
	<code>int fputs(char *line, FILE *fp)</code>
	<code>fputs</code> writes <code>line</code> to <code>fp</code>
	returns 0 for successful write
	(or EOF if error occurs, e.g. disk fills up)
	in the event of an error, we can use <code>perror</code> to print out exact error cause to <code>stderr</code>

<code>fgets</code> and <code>fputs</code> implementations from K&R (page 165)	
<pre>char *fgets(char *s, int n, FILE *iop) {     register int c;     register char *cs;     cs = s;     while (--n &gt; 0 &amp;&amp; (c = getc(iop)) != EOF)         if ((*cs++ = c) == '\n')             break;     *cs = '\0';     return (c == EOF &amp;&amp; cs == s) ? NULL : s; }  int fputs(char *s, FILE *iop) {     int c;     while (c = *s++)         putc(c, iop);     return ferror(iop) ? EOF : 0; }</pre>	

### MISCELLANEOUS FUNCTIONS (K&R, § 7.8)

#### STRING OPERATIONS

We've used many of these throughout the semester.	
<code>s</code> , <code>t</code> are <code>char *</code> (character pointers)	
<code>c</code> , <code>n</code> are ints	
<code>strcat(s,t)</code>	concatenate <code>t</code> to end of <code>s</code>
<code>strncat(s,t,n)</code>	concatenate <code>n</code> characters of <code>t</code> to end of <code>s</code>
<code>strcmp(s,t)</code>	return negative ( <code>s &lt; t</code> ) zero ( <code>s == t</code> ) positive ( <code>s &gt; t</code> )
<code>strncmp(s,t,n)</code>	same as <code>strcmp</code> but only in first <code>n</code> characters
<code>strcpy(s,t)</code>	copy <code>t</code> to <code>s</code>
<code>strncpy(s,t,n)</code>	copy at most <code>n</code> characters of <code>t</code> to <code>s</code>
<code>strlen(s)</code>	return length of <code>s</code>
<code>strchr(s,c)</code>	return pointer to first <code>c</code> in <code>s</code> , or NULL if not present
<code>strrchr(s,c)</code>	return pointer to last <code>c</code> in <code>s</code> , or NULL if not present

#### CLASS TESTING AND CONVERSION

We've used at least one of these.	
<code>c</code> is an int that can be represented as an unsigned char or EOF. These functions return int.	
<code>isalpha(c)</code>	non-zero if <code>c</code> is alphabetic, 0 if not
<code>isupper(c)</code>	non-zero if <code>c</code> is upper case, 0 if not
<code>islower(c)</code>	non-zero if <code>c</code> is lower case, 0 if not
<code>isdigit(c)</code>	non-zero if <code>c</code> is digit, 0 if not
<code>isalnum(c)</code>	non-zero if <code>isalpha(c)</code> or <code>isdigit(c)</code> , 0 if not
<code>isspace(c)</code>	non-zero if <code>c</code> is blank, tab, newline, return, formfeed, vertical tab
<code>toupper(c)</code>	return <code>c</code> converted to upper case
<code>tolower(c)</code>	return <code>c</code> converted to lower case

### MISCELLANEOUS

<code>int ungetc(int c, FILE *fp)</code>	
Like the <code>ungetc</code> function we used in the calcit homework, but limited to one char at a time.	
If successful, puts one character back to a stream, making it available for the next read operation, and returns the char it put back.	
If it fails, returns EOF and stream is unchanged.	
<code>int system(char *s)</code>	
Passes the string <code>s</code> to the environment for execution, then resumes execution of the current program.	
Examples:	
<pre>int a, b; char command[MAXCMD]; sprintf(command, "prog %d %d &gt; prog.out", a, b); system(command);</pre>	
Allows you to run a program compiled as <code>prog</code> that takes command line input with inputs <code>a</code> and <code>b</code> . You can then access the output file ( <code>prog.out</code> ) in the calling program.	
The return value is system-dependent. In UNIX, returns the value returned by <code>exit</code> .	

Storage Management	
<code>void *malloc(size_t n)</code>	We've used this a lot. Returns a <code>void</code> pointer to <code>n</code> bytes of uninitialized storage (or NULL if it fails)
<code>void*calloc(size_t n, size_t size)</code>	Returns a pointer to enough space for an array of <code>n</code> objects of size <code>size</code> bytes.
We must <code>cast</code> the returned pointer to the correct type of pointer for what we requested.	
When we're done with the requested memory, we call <code>free(pointer)</code> to free it.	

### MATHEMATICAL FUNCTIONS

An incomplete listing of the mathematical functions available in <code>&lt;math.h&gt;</code> :	
<code>sin(x)</code>	sine of <code>x</code> , <code>x</code> in radians
<code>cos(x)</code>	cosine of <code>x</code> , <code>x</code> in radians
<code>atan2(y,x)</code>	arctangent of <code>y/x</code> , in radians
<code>exp(x)</code>	exponential function $e^x$
<code>log(x)</code>	natural (base $e$ ) logarithm of <code>x</code> ( <code>x &gt; 0</code> )
<code>log10(x)</code>	common (base 10) logarithm of <code>x</code> ( <code>x &gt; 0</code> )
<code>pow(x,y)</code>	$x^y$
<code>sqrt(x)</code>	square root of <code>x</code> ( <code>x &gt; 0</code> )
<code>fabs(x)</code>	absolute value of <code>x</code>
NOTE:	Remember that you must compile with the <code>math</code> library flag when using the <code>math</code> library: <code>gcc source.c -lm</code> (the <code>-lm</code> has to be at the end of the line)

### RANDOM NUMBER GENERATION

<code>int rand(void)</code>	
<code>rand()</code> returns a pseudo-random number in the range of 0 to <code>RAND_MAX</code> .	
<code>RAND_MAX</code> is defined in <code>&lt;stdlib.h&gt;</code> . Its value is implementation-dependent, but guaranteed $\geq 32,767$ .	
Example:	
one way to produce random floating point numbers	
<code>0 &lt;= random number &lt; 1</code>	
#define <code>frand()</code> ((double) <code>rand()</code> / ( <code>RAND_MAX</code> + 1.0))	
<code>void srand(unsigned int seed)</code>	
<code>srand</code> sets the seed value for <code>rand</code> . Often the seed value is based on the system clock (the number of seconds elapsed since 00:00:00 UTC, 1/1/1970).	

## QSORT

C's <stdlib.h> contains a `quicksort` implementation.

```
void qsort(void *base,
           size_t nitems,
           size_t size,
           int (*comp)(const void *,
                       const void*))
{
}
```

base	a pointer to the first element in the array to be sorted
nitems	the number of elements in the array to be sorted
size	the size (in bytes) of each element in the array
comp	function pointer to the compare used to sort

`qsort` has no idea what type of data it is sorting, this is why we must provide the size of each element.

So, if we have a basic compare function for ints:

```
int intcompare(int *i, int *j)
{
    return (*i - *j);
}
```

We can use `qsort` like this:

```
main ()
{
    int i;
    int a [10] = {8, 2, 9, 6, 5, 1, 3, 7, 4, 0};
    qsort(a, // we want to sort array a
          10, // there are 10 elements in a
          sizeof(int), // each element has size 4 bytes
          // and we want to use intcompare
          (int (*)(void *, void *)) intcompare
    );
    for (i = 0; i < 10; i++)
        printf("%d, ", a[i]);
}
```

## BSEARCH

C's <stdlib.h> contains a `binary search` implementation.

```
void *bsearch(const void *key,
              const void *base,
              size_t nitems,
              size_t size,
              int (*comp)(const void *, const void *))
{
}
```

key	pointer to the object we're searching for
base	pointer to the first item in the array we are searching in
nitems	the number of elements in base
size	the size of each element in base
comp	function pointer to the compare we're using

`bsearch` returns a pointer to an entry in the array that matches the key (if the key is not found, a NULL pointer is returned).
